

## <sup>1</sup> Appendix S1. Stability selection

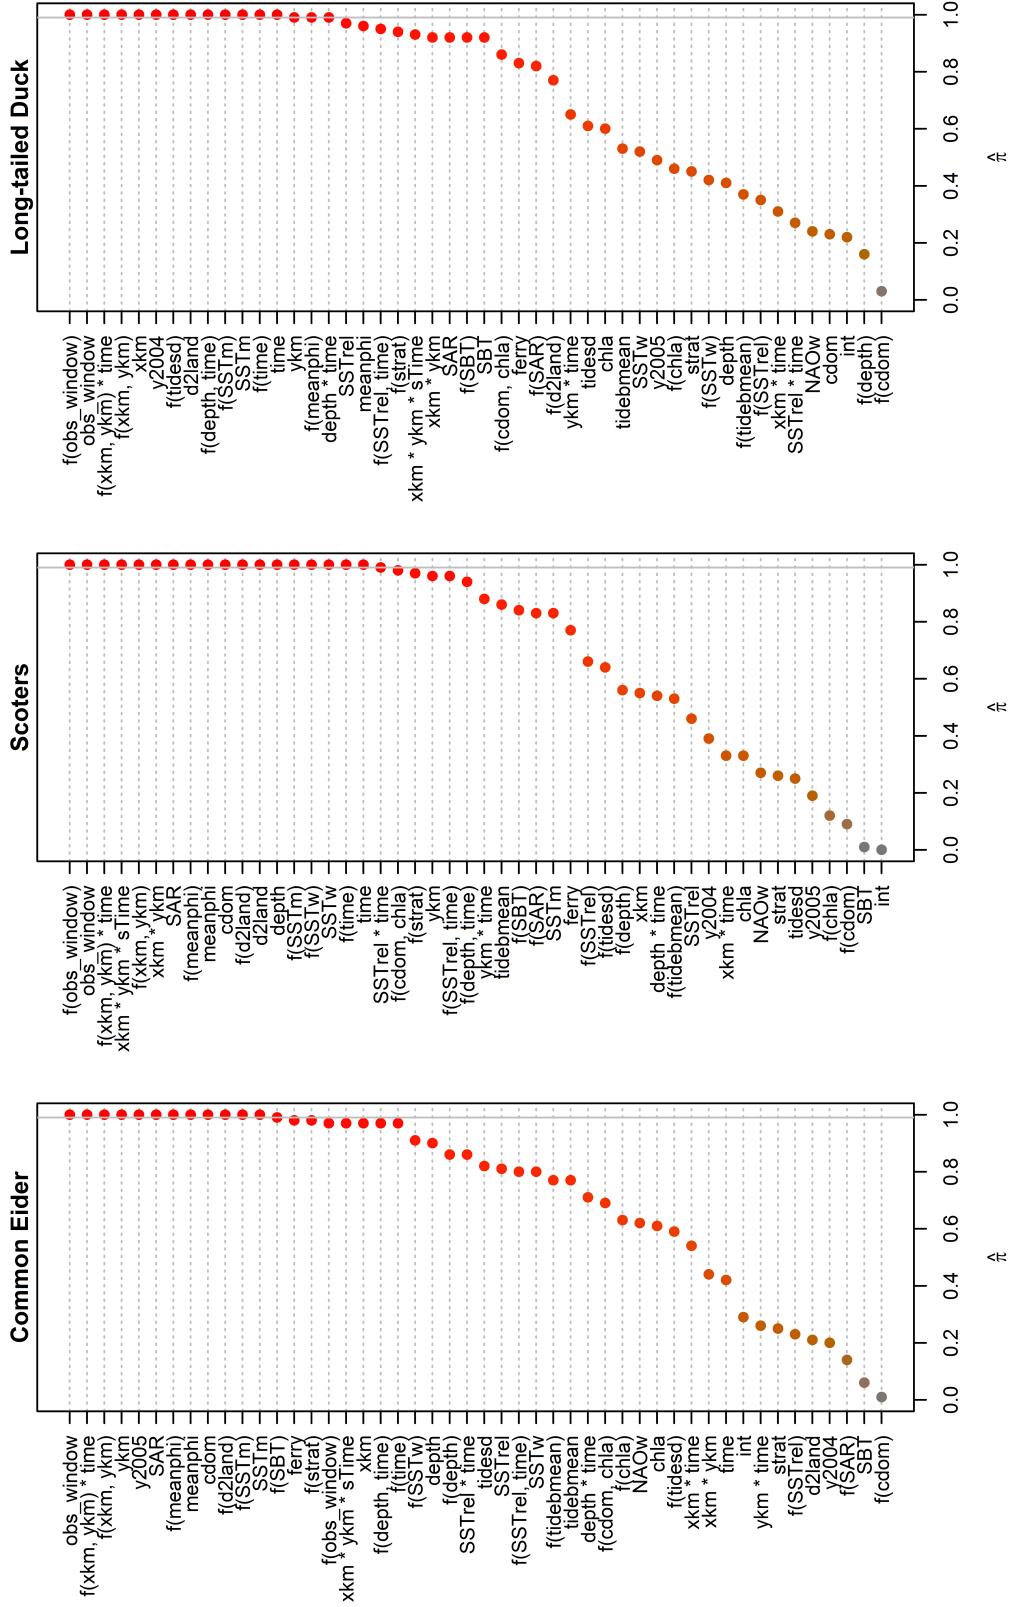

### <sup>2</sup> Methods

<sup>3</sup> We applied stability selection (Meinshausen and Bühlmann 2010, Shah and Samworth  
<sup>4</sup> 2013, see also Hofner et al. 2015 for details in the context of boosting) to identify base-  
<sup>5</sup> learners, and thus covariates, that were commonly selected in the majority of randomly  
<sup>6</sup> drawn subsamples of size  $\lfloor n/2 \rfloor$  of the data. As proposed by Shah and Samworth (2013),  
<sup>7</sup> we used  $B = 50$  complementary pairs subsamples (i.e., we randomly split the data into  
<sup>8</sup> two halves and used both to independently fit the model). This resulted in 100 total sub-  
<sup>9</sup> samples. We set the number of selected base-learners per boosting model ( $q$ ) to 35 and  
<sup>10</sup> established upper bounds of three and six for the occupancy and count model per-family  
<sup>11</sup> error rates (PFER), respectively. These error bounds corresponded to an upper bound of  
<sup>12</sup>  $\alpha = 0.062$  for the per-comparison error rate in both models. The different thresholds re-  
<sup>13</sup> flect the different number of base-learners in the two models; occupancy models contained  
<sup>14</sup> 48 base-learners while the count models contained twice as many base-learners (i.e., 48  
<sup>15</sup> each for the mean and overdispersion parameter). The choice of  $q$  is somewhat arbitrary;  
<sup>16</sup> it is chosen to be large enough to incorporate all important variables in the model (Hofner  
<sup>17</sup> et al. 2015). We used the unimodality assumption for the computation of the error bounds  
<sup>18</sup> in the occupancy and count models (Shah and Samworth 2013, Hofner et al. 2015).

### <sup>19</sup> Results

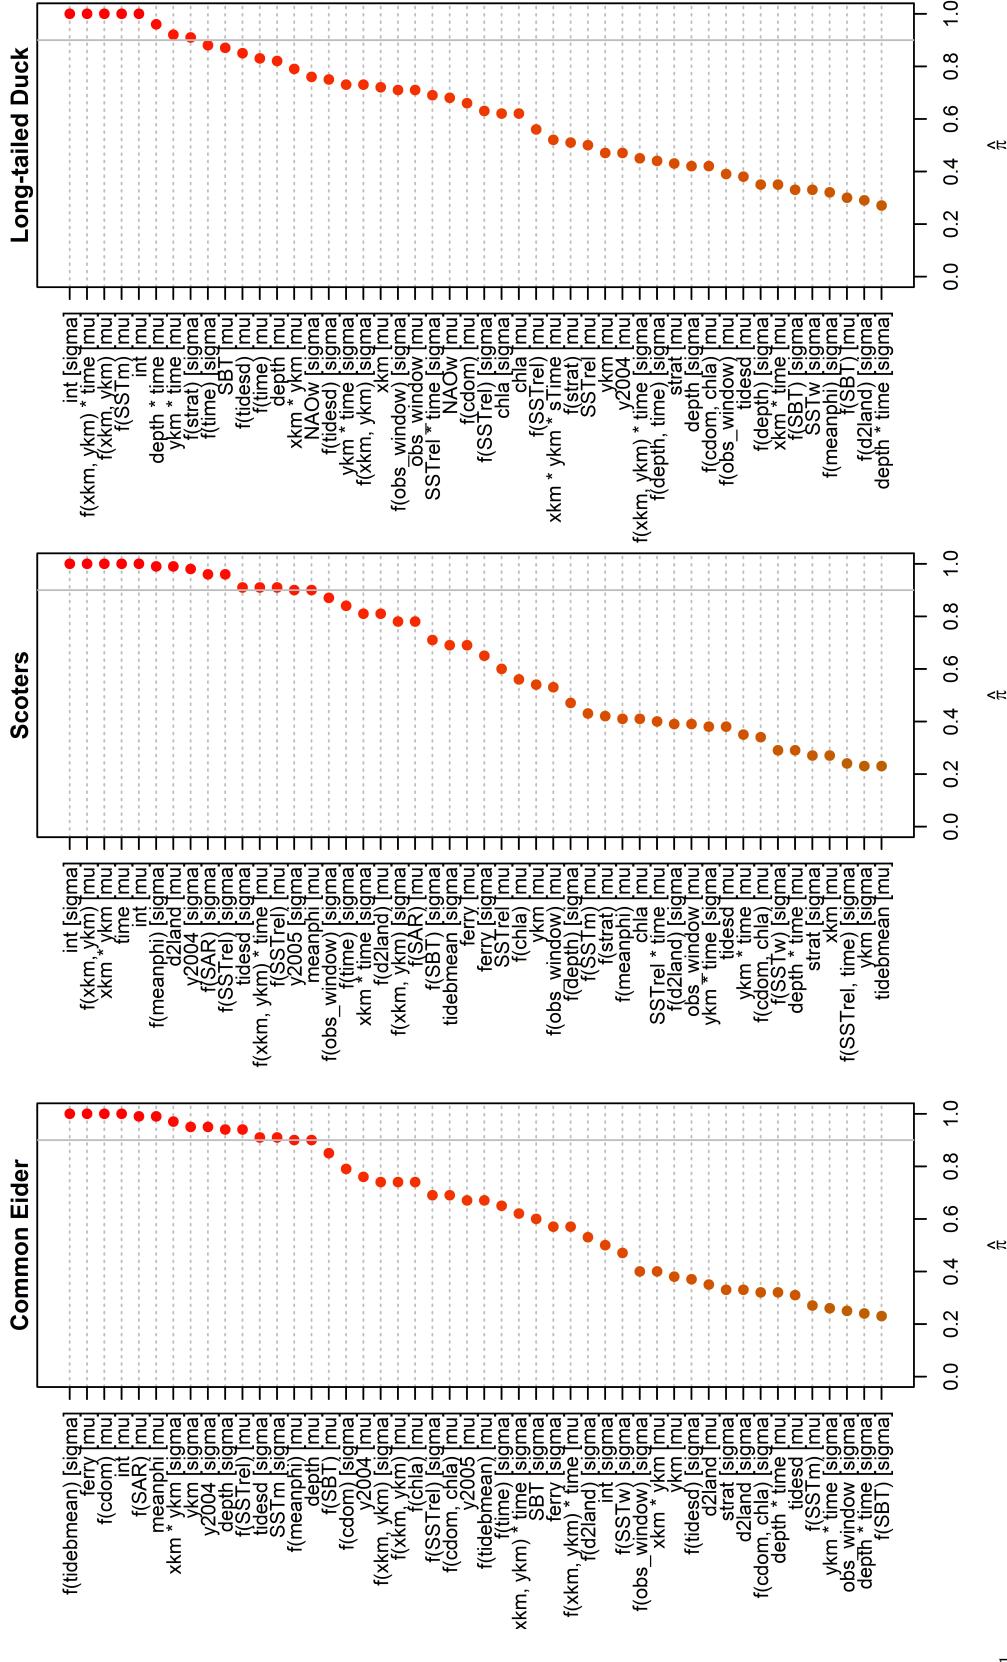

<sup>20</sup> *Occupancy models.*—Given our specifications ( $q = 35$ ; PFER upper-bound = 3, unimodal-  
<sup>21</sup> ity assumption), only base-learners selected in at least 99 of the 100 subsamples (i.e.,  $\pi_{\text{thr}}$   
<sup>22</sup> = 0.99) were identified as stable (Figure S1.1).

<sup>23</sup> *Count models.*—Given our specifications ( $q = 35$ ; PFER upper-bound = 6, unimodality  
<sup>24</sup> assumption), only base-learners selected in at least 90 of the 100 subsamples (i.e.,  $\pi_{\text{thr}}$   
<sup>25</sup> = 0.9) were identified as stable (Figure S1.2); this threshold applies to the simultaneous  
<sup>26</sup> selection of base-learners for the conditional mean ( $\mu$ ) and conditional overdispersion ( $\sigma$ ).

27

28 **Figure S1.1** Stability selection using complementary pairs subsampling and unimodality assumption for sea duck occupancy  
29 models. The number of selected base-learners in each model run was set to  $q = 35$ . Base-learners with selection frequencies  
30 above the threshold ( $\pi_{\text{thr}}$ ; vertical gray line) were considered stable with upper bound PFER = 3.

**Figure S1.2** Stability selection using complementary pairs subsampling and unimodality assumption for sea duck conditional count models. The number of selected base-learners in each model run was set to  $q = 35$ . Base-learners with selection frequencies above the threshold ( $\pi_{thr}$ ; vertical gray line) were considered stable with upper bound PFER = 6. Only the top 48 (of 96 total) base-learners are illustrated. Brackets indicate the parameter (conditional mean,  $mu$ , or overdispersion,  $sigma$ ) to which the base-learner applies.
